Marginal Propensity to Consume with Economic Shocks
- FIML Markov-Switching Model Analysis

Abstract

Hamilton’s Markov-switching model [5] was extended to the simultaneous equations model. A framework for an instrumental variable interpretation of full information maximum likelihood (FIML) by Hausman [4] can be used to deal with the problem of simultaneous equations based on the Hamilton filter [5]. A comparison of the proposed FIML Markov-switching model with the LIML Markov-switching models [1,2,3] revealed the LIML Markov-switching models to be a special case of the proposed FIML Markov-switching model, where all but the first equation were just identified. Moreover, the proposed Markov-switching model is a general form in simultaneous equations and covers a broad class of models that could not be handled previously. Excess sensitivity of marginal propensity to consume with big shocks, such as housing bubble bursts in 2008, can be determined by applying the proposed model to Campbell and Mankiw’s consumption function [6], and allowing for the possibility of structural breaks in the sensitivity of consumption growth to income growth.

Key Words : FIML, LIML, instrumental variable, simultaneous equation, Markov switching, Hamilton filter, consumption, income, bubble burst

1. Introduction

This paper deals with an important issue associated with a class of the Markov-switching model in the simultaneous equations. LIML (Limited Information Maximum Likelihood) Markov-switching models [1-3] estimate the parameters of a single equation. However, LIML models can be considered as a special case of the FIML (Full Information Maximum Likelihood) model where all but
the first equation are just identified.

This paper extends LIML Markov-switching models to a full set of structural simultaneous equations, essentially going from LIML to FIML with the addition to Markov-switching.

Using a framework for an instrumental variable interpretation of full information maximum likelihood by Hausman[4], this paper provides FIML Markov-switching model in the simultaneous equations.

The findings of this paper are that the proposed FIML Markov-switching model is a general form in the simultaneous equations and covers a broad class of models that could not be handled before. The advantage of the proposed FIML Markov-switching model is that we can deal with the problem of simultaneous equations based on the Hamilton filter[5] and we can directly interpret the economic meaning of the estimated parameters without transformation of the model and the proposed FIML Markov-switching model don’t need another step to correct for the standard errors of the parameter estimates such as Kim’s LIML Markov-switching model[2].

In this paper the Campbell–Mankiw consumption on income problem[6] is used as an illustration.

This paper has been divided into five sections. Section 2 presents the model specification. Section 3 compares the proposed FIML Markov-switching model to LIML Markov-switching models[1,3]. Section 4 summarizes the empirical results. Section 5 concludes this paper.

2. Model Specification

In order to get a consistent estimation of the parameters of the Markov-switching model in the simultaneous equations, we consider the following FIML Markov-switching model.

\[
YB_{St} + Z\Gamma_{St} = U_{St},
\]

\[
U_{St} \sim i.i.d. \mathcal{N}(0, \Sigma_{St} \otimes I_T)
\]

where

\[
Y = \begin{bmatrix}
Y_{11} & Y_{12} & \cdots & Y_{1M} \\
Y_{21} & Y_{22} & \cdots & Y_{2M} \\
\vdots & \vdots & \ddots & \vdots \\
Y_{T1} & Y_{T2} & \cdots & Y_{TM}
\end{bmatrix} \begin{bmatrix}
y_1 \\
y_2 \\
\vdots \\
y_T
\end{bmatrix}
\]

\[
B_{St} = \begin{bmatrix}
\beta_{11, St1} & \beta_{12, St2} & \cdots & \beta_{1M, StM} \\
\beta_{21, St1} & \beta_{22, St2} & \cdots & \beta_{2M, StM} \\
\vdots & \vdots & \ddots & \vdots \\
\beta_{M1, St1} & \beta_{M2, St2} & \cdots & \beta_{MM, StM}
\end{bmatrix}
\]

\[
Z = \begin{bmatrix}
Z_{11} & Z_{12} & \cdots & Z_{1K} \\
Z_{21} & Z_{22} & \cdots & Z_{2K} \\
\vdots & \vdots & \ddots & \vdots \\
Z_{T1} & Z_{T2} & \cdots & Z_{TK}
\end{bmatrix} \begin{bmatrix}
z_1 \\
z_2 \\
\vdots \\
z_T
\end{bmatrix}
\]

\[
\Gamma_{St} = \begin{bmatrix}
\gamma_{11, St1} & \gamma_{12, St2} & \cdots & \gamma_{1M, StM} \\
\gamma_{21, St1} & \gamma_{22, St2} & \cdots & \gamma_{2M, StM} \\
\vdots & \vdots & \ddots & \vdots \\
\gamma_{K1, St1} & \gamma_{K2, St2} & \cdots & \gamma_{KM, StM}
\end{bmatrix}
\]

\[
U_{St} = \begin{bmatrix}
u_{11, St1} & u_{12, St2} & \cdots & u_{1M, StM} \\
u_{21, St1} & u_{22, St2} & \cdots & u_{2M, StM} \\
\vdots & \vdots & \ddots & \vdots \\
u_{T1, St1} & u_{T2, St2} & \cdots & u_{TM, StM}
\end{bmatrix}
\]

\[
E(U'_{St} U_{St}) = E \begin{bmatrix}
u_{St1} \\
u_{St2} \\
\vdots \\
u_{StM}
\end{bmatrix} \begin{bmatrix}
u_{St1} & \nu_{St2} & \cdots & \nu_{StM}
\end{bmatrix} = \Sigma_{St} \otimes I_T
\]

\[
Y \text{ is the } T \times M \text{ matrix of jointly dependent variables, } B_{St} \text{ is an } M \times M \text{ matrix and nonsingular. } Z \text{ is the } T \times K \text{ matrix of predetermined variables, } \Gamma_{St} \text{ is }
\]
K x M matrix positive definite and \( \text{rank}(Z) = K \). \( U_{st} \) is \( T \times M \) matrix of the structural disturbances of the system. Thus, the model has \( M \) equations and \( T \) observations. The structural errors are assumed as a nonsingular \( M \)–variate normal (Gaussian) distribution. \( \sigma \) is the covariance of the error terms. \( \sum_{s} \) is a positive definite \( M \) by \( M \) matrix with no restrictions. It is assumed that all equations satisfy the rank condition for identification. Also if lagged endogenous variables are included as predetermined variables, the system is assumed to be stable. An orthogonality assumption, \( E(Z'U_{st}) = 0 \), between the predetermined variables and structural errors is required and, we assume the presence of contemporaneous correlation but no intertemporal correlation in (1). If we assume that the single Markov–switching variable \( S_t \) has an \( N \)-state, first–order Markov process, then we can write the transition probability matrix in the following way:

\[
p = \begin{bmatrix}
p_{11} & p_{12} & \cdots & p_{1N} \\
p_{21} & p_{22} & \cdots & p_{2N} \\
\vdots & \vdots & \ddots & \vdots \\
p_{N1} & p_{N2} & \cdots & p_{NN}
\end{bmatrix}
\]

where \( p_{ij} = \Pr(S_t = j | S_{t-1} = i) \) with \( \sum_{j=1}^{N} p_{ij} = 1 \) for all \( i \).

To include different first order Markov–switching variables \( S_{1t}, S_{2t}, S_{3t}, \ldots \), in the proposed model, we assume that the dynamics of an unobserved two–state, first order Markov–switching variables, \( S_{1t}, S_{2t}, S_{3t}, \ldots \) are independent and can be represented by a single Markov–switching variable, \( S_t \).

For example, if our model involves only two unobserved two–state first order Markov–switching variables such as \( S_{1t} \) and \( S_{2t} \). The dynamics of Markov–switching variables such as \( S_{1t}, S_{2t} \) can be represented by a single Markov–switching variable \( S_t \) in the following manner:

\[
S_t = 1 \quad \text{if} \quad S_{1t} = 0 \text{and} S_{2t} = 0
\]

\[
S_t = 2 \quad \text{if} \quad S_{1t} = 0 \text{and} S_{2t} = 1
\]

\[
S_t = 3 \quad \text{if} \quad S_{1t} = 1 \text{and} S_{2t} = 0
\]

\[
S_t = 4 \quad \text{if} \quad S_{1t} = 1 \text{and} S_{2t} = 1
\]

with \( p_{ij} = \Pr(S_t = j | S_{t-1} = i) \),

\[
\sum_{j=1}^{4} p_{ij} = 1
\]

Hausman[4] showed an instrumental variable interpretation of FIML for simultaneous equations where the function is maximized

\[
L(B, \Gamma; \Sigma) = (2\pi)^{-MT/2}|\Sigma|^{-T/2}|B^T| \exp\left[-\frac{1}{2} \text{tr}(YB + Z\Gamma)\Sigma^{-1}(YB + Z\Gamma)'\right] \]

\[
= (2\pi)^{-MT/2}|\Sigma|^{-T/2}|B^T| \exp\left[-\frac{1}{2} \sum_{i=1}^{T} (y_iB + z_i\Gamma)\Sigma^{-1}(y_iB + z_i\Gamma)'\right]
\]

where \( y_t \) is the \( t \)th row of the \( Y \) matrix. \( z_t \) is the \( t \)th row of the \( Z \) matrix.

To derive the FIML Markov–Switching Model in the simultaneous equations, we can obtain \( \Pr(S_t = j | \psi_t) \) by applying a Hamilton filter[5] as follows:

Step 1 :
At the beginning of the \( t \)th iteration, \( \Pr(S_{t-1} = i | \psi_{t-1}), \text{ } i = 0, 1, \ldots, N \) is given.

And, we calculate
Pr(S_t = j|\psi_{t-1})
= \sum_{i=1}^{N} Pr(S_{t-1} = i, S_t = j|\psi_{t-1})
= \sum_{i=1}^{N} Pr(S_t = j|S_{t-1} = i) \cdot Pr(S_{t-1} = i|\psi_{t-1})

where Pr(S_t = j|S_{t-1} = i),
i = 0, 1, \cdots, N, j = 0, 1, \cdots, N are the transition probabilities.

Step 2:
Consider the joint conditional density of \( y_t \) and unobserved \( S_t = j \) variable, which is the product of the conditional and marginal densities:

\[ f(y_t, S_t = j|\psi_{t-1}) = f(y_t|S_t = j, \psi_{t-1}) \cdot Pr(S_t = j|\psi_{t-1}) \]

from which the marginal density of \( y_t \) is obtained

\[ f(y_t|\psi_{t-1}) = \sum_{j=1}^{N} f(y_t|S_t = j, \psi_{t-1}) \cdot Pr(S_t = j|\psi_{t-1}) \]

where conditional density is obtained from (2):

\[ f(y_t|S_t = j, \psi_{t-1}) = (2\pi)^{-M/2} |\Sigma_{st}|^{-1/2} B_{st} \exp[-\frac{1}{2} (y_t B_{st} + z_t \Gamma_{st}) \Sigma_{st}^{-1} (y_t B_{st} + z_t \Gamma_{st})'] \]  \( (3) \)

\( \Sigma_{st} = \frac{1}{T} (YB_{st} + Z\Gamma_{st})' (YB_{st} + Z\Gamma_{st}) \)

\( y_t \) is the \( t \)th row of the \( Y \) matrix. \( z_t \) is the \( t \)th row of the \( Z \) matrix. \( B_{st} \) and \( \Gamma_{st} \) is obtained from (1).

Step 3:
Once \( y_t \) is observed at the end of time \( t \), we update the probability terms:

\[ Pr(S_t = j|\psi_t) = Pr(S_t = j|\psi_{t-1}, y_t) \]

\[ = \frac{f(S_t = j, y_t|\psi_{t-1})}{f(y_t|\psi_{t-1})} \]
\[ = \frac{f(y_t|S_t = j, \psi_{t-1}) \cdot Pr(S_t = j|\psi_{t-1})}{f(y_t|\psi_{t-1})} \]

As a byproduct of the above filter in Step 2 we obtain the log likelihood function:

\[ \ln L = \sum_{t=1}^{T} \ln f(y_t|\psi_{t-1}) \]

which can be maximized in respect to the parameters of the model.

3. Comparison of the proposed FIML MS model to LIML MS models

To solve the problems of the regressors being correlated with the disturbance in the Markov-switching models, we can adopt two models.

The first model is LIML Markov-switching model proposed by Kim[1,2] and Spagnolo, et al.[3]. The characteristics of LIML Markov-switching models
estimate the parameters of a single equation.

In the case of LIML Markov-switching model, the result of the "standard" estimation method proposed by Spagnolo, et al.\[3\] is mathematically identical to the "alternative" estimation method proposed by Kim\[1\].

The second model is FIML Markov-switching model which we provide in this paper. The merit of the FIML Markov-switching model is that it provides the complete model in the case of simultaneous equations problem and solves the joint endogeneity of variables in simultaneous equations concurrently.

The gain of the reduction in the asymptotic covariance matrix in the FIML Markov-switching model brings with it an increased risk of inconsistent estimation. However, LIML Markov-switching models can be considered as special cases of the proposed FIML Markov-switching model where all but the first equation are just identified. Moreover, Kim’s LIML Markov-switching model\[1,2\] needs transformation of the model by Cholesky decomposition of the covariance matrix and Spagnolo, et al.\[3\] LIML Markov-switching model needs transformation of the model by \(0\) constraints on the covariance matrix of the residuals, whereas the proposed FIML Markov-switching model is a general model which does not need any transformation.

Spagnolo, et al.\[3\] LIML Markov-switching model is very similar to the example of Hausman\[7\] equation (2.3) which has \(0\) constraints on the covariance matrix of the residuals in the simultaneous equations.

When we compare the proposed FIML Markov-switching model to Kim’s LIML Markov-switching model\[1\], we find the proposed FIML Markov-switching model is mathematically identical to Kim’s LIML Markov-switching model\[1\] with \(|B_{S1}^T| = 1\) in equation (3). However, the difference between the proposed FIML model to Kim’s LIML Markov-switching model is that Kim’s LIML model needs another step to correct for the standard errors of the parameter estimates. Moreover, the proposed FIML Markov-switching model includes not only the case of \(|B_{S1}^T| = 1\), but also the case of \(|B_{S1}^T| \neq 1\). So Kim’s LIML Markov-switching model\[1\] can be considered as a special case of the proposed FIML Markov-switching model.

### 4. Application

Let’s consider Campbell and Mankiw’s consumption model\[6\] as an example given by equations (4) and (5).

\[
\Delta C_t = \alpha + \beta \Delta Y_t + e_t \tag{4}
\]

\[
\Delta Y_t = z_t' \delta + \nu_t \tag{5}
\]

where \(Y_t\) is the log of per-capita disposable income; \(C_t\) is the log of per-capita consumption on non-durable goods and services; \(e_t\) and \(\nu_t\) are correlated; \(z_t'\) is a vector of instrumental variables not correlated with \(e_t\).

Following Campbell and Mankiw\[6\], the vector of instrumental variables employed \(z_t'\) is given by

\[
[\Delta Y_{t-2}, \Delta Y_{t-3}, \Delta Y_{t-4}, \Delta C_{t-2}, \Delta C_{t-3}, \Delta C_{t-4}, \Delta i_{t-2}, \Delta i_{t-3}, \Delta i_{t-4}]
\]

where \(i_t\) is the first difference of the three-month T-bill rate. \(\beta\) is interpreted as a fraction of aggregate income that accrues to individuals who consume their current income in the presence of liquidity constraints.

In equation (4) it can be seen that \(e_t\) and \(\Delta Y_t\) are positively correlated, therefore \(\beta\) would be overestimated by OLS. To solve the problem of the bias in the simultaneous equations (4) and (5), we can adapt the likelihood function of the simultaneous equations model in equation (2) following Hausman’s instrumental variable interpretation of FIM\[4\].
While there seems to be a consensus that there is excess sensitivity of consumption to current income which is represented by $\beta$, there is a disagreement as to the source of this excess sensitivity and whether $\beta$ is constant or not.

In equation (4), Campbell and Mankiw[6] assume the constant $\beta$. However, in light of the literature on precautionary saving, the parameter $\beta$ in equation (4) can also change when the economy is facing a great degree of uncertainty. Kimball[8] predicts that the marginal propensity to consume should have been higher in the 1970’s, when there was great uncertainty about the future rate of productivity growth. Kim[2] adopts a two-step MLE procedure with a three-state Markov switching model using the same variables in Campbell and Mankiw[6] for quarterly real data from FRED, collected by the Federal Reserve Bank of St. Louis. Kim[2] found that in the 1970’s and 1980’s, during which time uncertainty in future income growth was highest, the measure of sensitivity was highest and statistically significant while it was not statistically significant in the rest of the sample.

Taking these into consideration in this paper, we try to find out whether $\beta$ is really constant or not. To do this, first we extend equations (4) and (5) in the following way which adopts simple two-state Markov switching parameters in order to incorporate structural breaks.

\[
\Delta C_t = \alpha_{st} + \beta_{st} \Delta Y_t + e_{st} \\
\Delta Y_t = z_t \delta + \nu_t
\]  \hspace{1cm} (6)  \hspace{1cm} (7)

where

\[
\alpha_{st} = \alpha_1 S_t + \alpha_0 (1 - S_t) \\
\beta_{st} = \beta_1 S_t + \beta_0 (1 - S_t) \\
e_{st} \sim i.i.d. N(0, \sigma_{st})
\]

\[
Pr (S_t = 0 | S_{t-1} = 0) = q \\
Pr (S_t = 1 | S_{t-1} = 1) = p
\]

\[
z_t = [\Delta Y_{t-2}, \Delta Y_{t-3}, \Delta Y_{t-4}, \Delta C_{t-2}, \Delta C_{t-3}, \Delta C_{t-4}, \Delta i_{t-2}, \Delta i_{t-3}, \Delta i_{t-4}]
\]

\[
\delta = [\phi_1, \phi_2, \phi_3, \phi_4, \phi_5, \phi_6, \phi_7, \phi_8, \phi_9]
\]

To solve the equations (6)-(7) together, we can rewrite them as follows:

\[
[\Delta C_t, \Delta Y_t] \left[\begin{array}{c}
1 \\
- \beta_{st} \\
1
\end{array}\right] - z_t \left[\begin{array}{c}
0 \\
\phi_1 \\
\phi_2
\end{array}\right] - [\alpha_{st} 0] = U_{st}
\]

where

\[
U_{st} \sim i.i.d. N(0, \sum_{st} \otimes I_T)
\]

\[
\sum_{st} = \begin{bmatrix}
\sigma_{st} & \sigma_{st,2} \\
\sigma_{st,2} & \sigma_{st,2}
\end{bmatrix}
\]

\[
\alpha_{st} = \alpha_1 S_t + \alpha_0 (1 - S_t) \\
\beta_{st} = \beta_1 S_t + \beta_0 (1 - S_t) \\
\sigma_{st} = \sigma_1 S_t + \sigma_0 (1 - S_t)
\]

\[
Pr (S_t = 0 | S_{t-1} = 0) = q \\
Pr (S_t = 1 | S_{t-1} = 1) = p
\]

Fig. 1 depicts the relationship between Consumption $\Delta C_t$ and Income $\Delta Y_t$.

Fig. 2 depicts the two-state FIML Markov switching probabilities.

Fig. 3 depicts the two-state Kim’s LIML Markov switching probabilities.
Table I reports estimation results for the proposed FIML Markov-switching model and LIML Markov-switching models.

The coefficients $\beta_0$, $\beta_1$ of the FIML Markov-switching model are significant, and the degree of the upward movements is large, from 0.47 ($= \beta_0$) to 0.65 ($= \beta_1$).

The coefficients $\sigma_{0,2}$, $\sigma_{1,2}$ of the FIML Markov-switching model are also significant. So, we can assume marginal propensity to consumption $\beta$ is not constant because the difference between $\beta_0$ and $\beta_1$ is large.

This result is same as the result of LIML Markov-switching models. The coefficients $\beta_0$, $\beta_1$ of Kim’s LIML Markov-switching model are significant, and the degree of the upward movements is large, from 0.29 ($= \beta_0$) to 0.57 ($= \beta_1$). The coefficients $\gamma_0$, $\gamma_1$ are significant.
of Kim’s LIML Markov-switching model are also significant.

From the results of the FIML Markov-switching model and LIML Markov-switching models, we can conclude that marginal propensity to consumption $\beta$ is not constant.

From Figure 4, we can find that the inferred probabilities $P_r(S_t = 1|S_{t-1} = 1) = p$ of the FIML and Kim’s LIML Markov switching model are very similar to those of LIML Markov switching models. However, the inferred probabilities $P_r(S_t = 1|S_{t-1} = 1) = p$ of the FIML Markov switching model and LIML Markov switching models accord with U.S recessionary dates after 1990. Especially we can find that a excess sensitivity of marginal propensity to consumption with big shocks such as housing bubble bursts in 2008.

We can also find that the inferred probabilities $P_r(S_t = 1|S_{t-1} = 1) = p$ are not consistent with Kimball[8], who suggests that the marginal propensity to consumption should have been higher in the 1970’s when there was great uncertainty about the future rate of productivity and income growth after two major OPEC oil shocks in 1973-1974 and 1979-1980.

5. Conclusion

In this paper, Hamilton’s(1989) Markov-switching model is extended to the simultaneous equations.

The proposed FIML Markov-switching model is applied to Campbell and Mankiw’s consumption function[6], by allowing for possibilities of structural breaks in the sensitivity of consumption growth to the income growth. From the empirical results of the FIML Markov-switching model and LIML Markov-switching models, we can conclude that marginal propensity to consumption $\beta$ is not constant. Especially we can also find that a excess sensitivity of marginal propensity to consume with big shocks such as housing bubble bursts in 2008.

Appendix I

1. THE SPECIAL CASE OF THE MARKOV–SWITCHING MODEL

In this section, we discuss representation of the special case of the Markov–switching model. Error terms are autocorrelated with AR(1). The model needs instrumental variables. The dynamics can be represented in the following manner:

$$y_t = Y_t \beta_{st} + X_t \alpha_{st} + e_{st}$$

where $e_{st} = \phi e_{st-1} + v_{st}$

$$Y_t = Y_{t-1} \theta_1 + Z_t \theta_2 + \omega_t$$

$$\alpha_{st} = \alpha_1 S_t + \alpha_0 (1 - S_t)$$

$$\beta_{st} = \beta_1 S_t + \beta_0 (1 - S_t)$$

$$e_{st} \sim i.i.d. N(0, \sigma_{st})$$

$$\sigma_{st} = \sigma_1 S_t + \sigma_0 (1 - S_t)$$

$$Pr(S_t = 0|S_{t-1} = 0) = q$$

$$Pr(S_t = 1|S_{t-1} = 1) = p$$

$$E(w_t v_{st}) \neq 0 \rightarrow E(Y_t e_{st}) \neq 0 \rightarrow E(Y_t v_{st}) \neq 0$$

where $y_t$ is T x 1. The endogenous explanatory variable $Y_t = [y_{t2}, \cdots, y_{tM}]$ is T x (M-1) and $\beta_{st}$ is (M-1) x 1. The exogenous explanatory variable $X_t = [x_{t1}, \cdots, x_{tK1}]$ is T x K1 and $\alpha_{st}$ is K1 x 1. $e_{st}$ is T x 1. $Y_{t-1}$ is T x (M-1) and $\theta_1$ is (M-1) x (M-1). $Z_t = [z_{t1}, \cdots, z_{tK2}]$ is T x K2 and $\theta_2$ is K2x(M-1). We can consider $Y_{t-1}$ and $Z_t$ together as the instrumental variables in the equation (9) because of $E(Y_t v_{st}) \neq 0$. 

6572
2. COMPARISON BETWEEN STANDARD AND ALTERNATIVE INSTRUMENTAL VARIABLE ESTIMATION

In equation (8) it can be seen that \( e_{st} \) and \( Y_t \) are correlated. The procedure to derive a Markov–switching model is as follows:

\[
y_t = Y_t \beta_{st} + X_t \alpha_{st} + e_{st} \quad (8)
\]

\[
\phi y_{t-1} = \phi Y_{t-1} \beta_{st} + \phi X_{t-1} \alpha_{st} + \phi e_{st-1} \quad (9)
\]

After we calculate equation (8)–(10), we obtained the following Markov-switching model.

\[
y_t = \phi y_{t-1} + (Y_t - \phi Y_{t-1}) \beta_{st} + (X_t - \phi X_{t-1}) \alpha_{st} + v_{st} \quad (10)
\]

\[
(\phi y_{t-1} + (Y_t - \phi Y_{t-1}) \beta_{st} + (X_t - \phi X_{t-1}) \alpha_{st} + v_{st}) = \phi y_{t-1} + (Y_t - \phi Y_{t-1}) \beta_{st} + (X_t - \phi X_{t-1}) \alpha_{st} + v_{st} \quad (11)
\]

The standard instrumental variable estimation method proposed by Spagnolo, et al.[3] needs the following two-step procedure.

Step 1: Regress \( Y_t \) on \( Y_{t-1}, Z_t \) and get residual \( \hat{w}_t \) from the equation (9).

\[
\hat{w}_t = Y_t - Y_{t-1} \hat{\beta}_1 - Z_t \hat{\theta}_2
\]

Step 2: Insert residual \( \hat{w}_t \) to the equation (11) and get the following regression

\[
y_t = \phi y_{t-1} + (Y_t - \phi Y_{t-1}) \beta_{st} + (X_t - \phi X_{t-1}) \alpha_{st} + \hat{w}_t \lambda_{st} + v_{st} \quad (12)
\]

In order to show that equation (12) and (13) are mathematically identical, we need the following procedure from equation (12).

First, we get \( Y_t = \hat{Y}_t + \hat{w}_t \).

Second, insert \( \hat{Y}_t = Y_t - \hat{w}_t \) to the equation (12), then we can get the following regression

\[
y_t = \phi y_{t-1} + (\hat{Y}_t - \phi Y_{t-1}) \beta_{st} + (X_t - \phi X_{t-1}) \alpha_{st} + \hat{w}_t (-\beta_{st}) + v_{st} \quad (13)
\]

The equation (14) is mathematically identical to the equation (13) with \( \lambda_{st} = (-\beta_{st}) \).

This result shows that the two estimation methods are mathematically identical even in the special case of the Markov–switching model.

Appendix II

1. COMPARISON OF THE PROPOSED FIML MODEL TO KIM’S LIML MODEL[1]

In order to show that Kim’s LIML Markov–switching model[1] is a special case of the
proposed FIML Markov-switching model, we can consider the following Markov-switching model

\[ y_t = Y_t \beta_{st} + X_t \alpha_{st} + e_{st} \]  \hspace{1cm} (15)

\[ Y_t = Z_{t1} \Pi_1 + Z_{t2} \Pi_2 + v_t \]  \hspace{1cm} (16)

In equation (15), \( y_t \) is \( T \times 1 \). The endogenous explanatory variable \( Y_t = [y_{t1}, \ldots, y_{tM}] \) is \( T \times (M-1) \) and \( \beta_{st} \) is \( (M-1) \times 1 \). The exogenous explanatory variable \( X_t = [x_{t1}, \ldots, x_{tK1}] \) is \( T \times K1 \) and \( \alpha_{st} \) is \( K1 \times 1 \). The error term \( e_{st} \) is \( T \times 1 \). The reduced form of the equation in (16) has the instrumental variables \( \varphi_{st} \) and \( \varphi_{st} \).

\[ \Omega^{-1} = \begin{bmatrix} 1 & 0 \\ - \delta_{st} & \Omega^{-1} \end{bmatrix} \]

where

\[ \varphi_{st} = Var(e_{st}), \quad \Omega^{-1} = Var(v_t) \]

From equations (15) and (16), we obtain the likelihood function in the simultaneous equation

\[ L(\Phi) = (2\pi)^{-MT/2} |\Omega|^{-T/2} |B_{st}^T|. \]

\[ \exp[-\frac{1}{2} tr(YB_{st} - RII)^{-1}(YB_{st} - RII)'] \]

\[ = (2\pi)^{-MT/2} |\Omega|^{-T/2}. \]

\[ \exp tr[-\frac{1}{2}(Q - RII)'(Q - RII)\Omega^{-1}] \]  \hspace{1cm} (18)

where

\[ \Phi = (\beta_{st}, \alpha_{st}, \Pi_1, \Pi_2, \sigma_{st}, \Omega_2, \delta_{st}), \]

\[ Q = YB_{st} = (y_t - Y_t \beta_{st}, Y_t) \]

\[ \Omega^{-1} = \begin{bmatrix} 1 & 0 \\ - \delta_{st} & \Omega^{-1} \end{bmatrix} \]

\[ \sigma_{st} = Var(e_{st}), \quad \delta_{st} = Cov(e_{st}, v_t), \]

\[ \Omega_2 = Var(v_t), \]

\[ \text{“exptr” denotes “exponential and trace”} \]

We can obtain \( \Omega^{-1} \) by factoring as suggested by Radchenko et al.[9] as follows,

\[ \Omega^{-1} = \begin{bmatrix} 1 \quad 0 \\ - \delta_{st} & \Omega^{-1} \end{bmatrix} \]

Then, the likelihood function in (18) may be transformed into

\[ L(\Phi) = (2\pi)^{-MT/2} |\Omega_2|^{-T/2} \cdot \exp[-\frac{1}{2} tr(Y_t - Z_{t1} \Pi_1 - Z_{t2} \Pi_2)'] \]

\[ \cdot \exp[-\frac{1}{2} w_{st}(y_t - Y_t \beta_{st} - X_t \alpha_{st} - v_t \lambda_{st})'] \]

\[ = (2\pi)^{-MT/2} |\Omega_2|^{-T/2}. \]

\[ \exp tr[-\frac{1}{2}(Q - RII)'(Q - RII)\Omega^{-1}] \]  \hspace{1cm} (19)

where

\[ w_{st} = \sigma_{st} - \delta_{st} \Omega_2^{-1} \delta_{st} = \sigma_{st} (1 - \rho_{st}^2) \]

\[ \rho_{st} = \delta_{st} \Omega_2^{-1} \delta_{st} / \sigma_{st} \]

\[ |B_{st}^T| = 1 \quad , \lambda_{st} = \Omega_2^{-1} \delta_{st}, \quad \text{and} \]

\[ \hat{v}_t = Y_t - \hat{Y}_t \]

The equation (18) of the proposed FIML Markov-switching model is mathematically identical to the equation (19) of Kim’s LIML Markov-switching model[1] with
As Kim’s LIML Markov-switching model uses 
\[ w_{st} = \sigma_{st} - \delta_{st} \Omega_2^{-1} \delta_{st} = \sigma_{st} (1 - \rho^2_{st}) \] instead of \( \sigma_{st} \). Kim’s LIML Markov-switching model needs another step to correct for the standard errors of the parameter estimates such as Kim(2) but the proposed FIML Markov-switching model doesn’t need another step to correct for the standard errors of the parameter estimates. Moreover, the proposed FIML Markov-switching model includes the case of in equation. \( B_{st}^T \neq 1 \) (18).

So, Kim’s LIML Markov-switching models can be considered as special cases of the proposed FIML Markov-switching model.
